

L03 Steven Ford's Reflection

1. Which type of machine learning (supervised/unsupervised/reinforcement) interests you most and why?
2. What was the most challenging part of the ML workflow for you?
3. How might you apply these concepts to a problem in your field of interest?
4. What questions do you have about machine learning that you'd like to explore further?

1. Reinforcement learning interests me the most as it's used for the most advanced model applications like video game simulation, self-driving cars and robotics.
2. I think that because of my lack of coding background, I struggle the most with understanding what my code is doing in the machine learning workflow. It feels like magic to me when I'm just following instructions and then I get an accurate result or have to look up how to debug my code. I think aside from the coding, I don't really understand how to get different datasets into the program. I have the idea they're downloaded on another source but I'm not sure how to do that or my limitations on it.
3. Data evaluation can be applicable any field to find commonalities that would infer how certain parts work together or against each other.
4. I'm starting to learn python on my own to help my lack of coding experience, so I won't ask about coding but rather about datasets. I'm thinking of making a spam email detecting program in a supervised learning environment, but I'd imagine that would be the most essential step is to find a reliable dataset that my model could learn from.
